2.3 SUMMARY OF TEST REPORT

MANUFACTURER:	Waverider
MODEL:	NCL 1100
SERIAL:	pre-production
DESCRIPTION:	SPREAD SPECTRUM BRIDGE MODULE
FREQUENCY RANGE:	2400-2483.5

The Waverider NCL-1100 was found to **“meet”** the radiated emission specification of Title 47 CFR FCC, Part 15, subpart C. for an intentional radiator. The NCL 1100 was also evaluated to pat 15 for emissions as a class A digital product.

The NCL-1100 is a wireless data link, or bridge, that is intended for high speed data transfer via a 2.4 GHz spread spectrum transceiver. It is intended only for commercial and industrial users.

2.4 INTRODUCTION

During August, September and October of 1999, a series of Radiated and Conducted Emissions tests were performed on two sample models of the Waverider model NCL 1100, a spread spectrum transceiver module, designed for moderate distance data transmission. These tests were performed using the test procedures outlined in ANSI C63.4-1992 for intentional radiators, and in accordance with the requirements set forth in FCC Part 15.247 for a direct sequence spread spectrum transmitter. Tests were also performed as outlined in ANSI C63.4-1992 for non-intentional radiators, in order to verify compliance with the limits set forth in part 15.109 for and to allow verification of emissions for the digital section of the product. These tests were performed by Kenneth L. Boston, PE, of L. S. Compliance, Inc.

2.5 PURPOSE

The above mentioned tests were performed in order to determine the compliance of the Waverider model NCL-1100 with limits contained in various provisions of Title 47 CFR, FCC Part 15, including:

15.207	15.247b	15.247e
15.205	15.247c	15.109
15.247a2	15.247d	

All radiated emissions tests were performed to measure the emissions in the frequency bands described by the above sections, and to determine whether said emissions are below the limits established by the above sections. These tests were performed in accordance with the procedure described in the American National Standard for methods of measurement of Radio-Noise Emissions from Low-Voltage Electrical and Electronic Equipment in the Range of 9 kHz to 40 GHz (ANSI C63.4-1992). Another document used as reference for the EMI receiver specification was the International Special Committee on Radio Interference (CISPR) number 16-1 (1993). Measurement technique guidelines found in Appendix C to FCC 97-114 were also consulted.

2.6 Power Output Test Performed

For the 15.247b measurement, the output of the Waverider model NCL 1100 module, including bandpass filter and lightning arrestor, was connected via a short jumper cable created only for this measurement, into the input of the HP E4407B Spectrum Analyzer. The unit was configured to run in a continuous transmit mode, with a pseudo-random test code supplied by software to provide modulation. The HP receiver was set to a 5 MHz Bandwidth, and the transmitted signal was then stored, with the peak signal level stored. This power level was collected for the lowest, highest and middle channels and can be seen in the chart presented below.

CHANNEL	CENTER FREQ (MHz)	LIMIT (dBm)	MEASURED POWER (dBm)	MARGIN (dB)
1	2412	30 dBm	15.17	14.83
3	2432	30 dBm	15.66	14.34
6	2462	30 dBm	17.00	13.00

2.7 Conducted RF Test Setup and measurements

FCC part 15.247 (c) requires an antenna conducted measurement of conducted harmonic and spurious levels, as reference to the carrier frequency in a 100 kHz bandwidth. For this test, the video transmitter module was directly connected to the HP E4407B spectrum analyzer, through a very short coaxial cable and a 10 DB attenuator. Plots were then taken, with any noticeable spurious or harmonic signals identified. No significant levels at any spurious products could be found within -20 dBc of the fundamental of the transmitter. Signals that were observed were greater than 50 dB down. (in the 100 kHz bandwidth)

2.8 Occupied Bandwidth Measurements

The 6 dB bandwidth requirement found in 15.247.a.2 is a minimum of 500 kHz. Direct measurement of the transmitted signal, via a direct cabled connection to the HP E4407B analyzer, was then used to determine the signal bandwidth. For each of the representative channels, refer to the graphs found in Appendix C. From this data, the bandwidth of channel 6, which is the closest data to the specification limit, is 7.45 MHz, which is above the minimum of 500 kHz.

CHANNE L	CENTER FREQ (MHz)	MEASURED 6 dB BW (kHz)	MINIMUM LIMIT (kHz)
1	2412	8200	500
3	2432	7700	500
6	2462	7450	500

2.9 Power Spectral Density

In accordance with FCC part 15.247(d), the peak power spectral density should not exceed +8 dBm in any 3 kHz band. This measurement was performed along with the conducted power output readings performed as described in section 2.6. The peak output frequency for each representative frequency was scanned, with a 3 kHz bandwidth; until the peak signal level in the transmitted spectrum could be located. Since individual modulation products were identifiable, the highest level was measured and compared to the limit, and can be determined by inspection of the graphs found in Appendix C. The highest density was found to be no greater than 1.5 dBm, which is under the allowable limit by 6.5 dB.

CHANNE L	CENTER FREQ	MEASURED P	SPEC	MARGIN
1	2411.99	1.5dBm	+8.0dBm	6.5dB

3	2431.99	0.0dBm	+8.0dBm	8.0dB
6	2461.99	0.0dbm	+8.0dBm	8.0dB

2.10 Processing Gain

A report detailing the results of a jamming margin test performed upon a typical system containing the Harris Prism chipset is attached to this report, wherein the processing gain of the system was determined by using the CW jamming margin method. Because this product contains the same base-band processing chipset, reference is made to this report as fulfilling the processing gain requirement. The justification for this means of showing compliance is contained in an E-mail from the FCC engineering staff, a copy of which is found in appendix D. This test was performed within a screened room located on the L.S. Compliance facility, by Brian Petted, of L.S. Research, which is co-located with L. S. Compliance in Cedarburg.

2.11 RADIATED EMISSIONS TEST SETUP

The test sample was operated within the 3 meter Semi-Anechoic, FCC listed chamber located at L.S. Compliance in Cedarburg, WI. The sample was set up on a small fixture and placed on a wooden pedestal, which was centered on the flush-mounted 2m diameter metal turntable. The test sample was operated on its own [new] internal power supply. The test sample was configured to run in a continuous transmit mode during the 15.247 and 15.205 measurements. One test sample was set to operate on either channel 1 (2412Mhz), channel 3 (2432 MHz), or channel 6 (2462 MHz) while being tested as an intentional radiator, in order to determine compliance within the frequency band of 2400-2483.5 MHz, as dictated by FCC part 15.31m

Please refer to Section 2.15 for pictures of the test setup.

2.12 RADIATED EMISSION TEST PROCEDURE

The fundamental and spurious (harmonic) emissions of the transmitter were tested for compliance to Title 47 CFR, FCC Part 15.247c limits for Direct Sequence Spread Spectrum systems, and the 15.205 general limits, within the restricted bands. For the calculations used to determine the 1 meter limits, see Appendix A. The test sample was tested from the lowest frequency generated by the transmitter to the 10th harmonic of the fundamental frequency generated by the device. The appropriate limits were also observed where any spurious signals were located within any of the restricted bands as described in Part 15.205a. These frequencies, and their associated limits, are referenced in Section 2.14. The sample was positioned on an 80 CM high pedestal and placed in the 3 Meter chamber and the antenna mast was placed such that the antenna was either 1 meter or 3 meters from the test object. A biconical antenna was used to measure emissions from 30 to 200 MHz, a log periodic was used to measure emissions from 200 to 1000 MHz, and a double ridged waveguide horn was used to measure emissions above 1 GHz. The test object was set to operate in continuous transmit, and the resultant signals were maximized by rotating the turntable 360 degrees, and by raising and lowering the antenna between 1 and 4 meters. The test object was also given several different orientations to determine the maximum signal levels, using both

horizontal and vertical antenna polarities. Emissions above 5 GHz were also measured at a 1 meter separation, using the HP 8563E analyzer and 8348A preamplifier.

No significant emissions were found aside from the transmitter fundamental and some spurious signals. The unit was scanned for emissions, over the range 30 to 25000 MHz to establish compliance with Part 15.247c and 15.205 for the system. The results of the system measurements are found in Appendix B, with graphs of the signature scans found in Appendix

2.13 TEST EQUIPMENT UTILIZED FOR RADIATED EMISSIONS TEST

A list of the test equipment and antennas used for the tests can be found in Section 2.17, which includes the calibration information as well as the equipment description. All equipment is calibrated and used according to the user manuals supplied by the manufacturer. All antenna calibrations were performed at a N.I.S.T traceable site, and the resultant correction factors were entered into the Hewlett Packard 8546A EMI receiver software database. The connecting cables used were also measured for loss using a calibrated signal generator and the HP 8546A EMI receiver. The resulting loss factors were entered into the HP 8546A database. This allowed for automatic changes in the antenna correction factor, as well as cable loss or other corrections, to be added to the EMI receiver display while taking measurements. Thus, the resulting data taken from the HP 8546A is an actual reading and can be entered into the database as a corrected meter reading. The HP 8546A EMI receiver was operated with a bandwidth of 120 kHz when receiving signals below 1 GHz, and with a bandwidth of 1 MHz when receiving signals above 1 GHz, in accordance with CISPR 16. Both the peak and Quasi-peak detector functions were used.

For measurements in the upper microwave region, a HP E4407B Spectrum analyzer was utilized. Being that this instrument is an integrated system, all antenna factors, cable factors, and preamplifier gain factors are stored and recalled when initially calibrated and configured for use. Data appearing on the screen and measured during emissions testing is then presented as corrected readings. During emissions testing, signals where significant levels were noted were measured using the 1 MHz IF bandwidth, and a 10 or 100 Hz video bandwidth, resulting in an average measurement mode of the analyzer. During Tx/Rx switching modes, the video bandwidth was raised to 1 MHz, and peaks were compared to the Average limits, plus 20 dB. Signal levels were also inspected using the 100 kHz bandwidth during conducted emission testing, and compared to the maximum radiated signal in a 100 kHz bandwidth of the fundamental modulated carrier for the three channels tested.

2.14 - Restricted Bands affecting this product

3 Meter limits

Frequency (MHz)	Limit (μV)	Limit (dB/μV/m)
2310-2390	500	54.0
2483.5-2500	500	54.0
2655-2900	500	54.0

View of the Waverider NCL 1000 module during conducted emission testing.

2.16 SUMMARY OF RESULTS AND CONCLUSIONS

Based on the procedures outlined in this report, and the test results included in appendices B and C, it can be determined that the Waverider NCL 1000 module does **“meet”** the emission requirements of Title 47 CFR, FCC Part 15 Subpart C for an intentional radiator. Some of the emissions in the restricted bands immediately adjacent to the 2.4 GHz ISM are within 4 dB of the limits respectively, and could be found to be over the limits if these samples, or others were to be tested by another agency.

During the testing, it was determined that an additional 2 pole filter for the ISM band would be required in the RF output path, in addition to the existing 2 pole filter. Therefore a Murata 2447F BPF was installed in the output cable, and will be required to be integrated along with the present band-pass filter in the cast aluminum box that contains the filter, resulting in a four pole band-pass filter.

The enclosed test results pertain to the samples of the test item listed, and only for the tests performed on the data sheets. Any subsequent modification or changes to the test items could invalidate the data contained herein, and could therefore invalidate the findings of this report.

APPENDIX A:

SAMPLE CALCULATIONS

Manufacturer: Waverider
Model: NCL 1000
Serial Number(s): preproduction

Calculation of Radiated Emissions limits for FCC Part 15.205 (above 1 GHz)

The following table depicts the limits for spurious products for an intentional radiator: Limits are included which are established at a measurement distance of 3 meters and also limits corrected for a 1 meter measurement distance, which are extrapolated from the 3 meter limit.

Frequency (MHz)	3m limit (dB μV/m)	1m limit (dB μV/m)
960 MHz up	54	63.54

- The 1 meter limits were calculated by adding a factor of 9.54 dB, derived from:

$$20\log_{10}(3/1) = 9.54 \text{ dB } \mu\text{V/m}$$

$$1\text{m limit} = 3\text{m limit} + \text{factor}$$

$$= 54 \text{ dB } \mu\text{V/m} + 9.54 \text{ dB } \mu\text{V/m}$$

$$= 63.54 \text{ dB } \mu\text{V/m}$$

Tx channel 6, 2.31-2.39 GHz, vertical polarity, 1 meter separation

Tx channel 1, 2.483-2.5 GHz, vertical polarity, 1 meter separation

Tx channel 3, 2.483-2.5 GHz, vertical polarity, 1 meter separation

FCC ID : OOX-NCL1100

Tx channel 6, 2.483-2.5 GHz, vertical polarity, 1 meter separation

Tx channel 4, 2.5-5 GHz, vertical Polarity

FCC ID : OOX-NCL1100

Tx channel 4; 1.0-2.31 GHz, vertical Polarity

FCC ID : OOX-NCL1100

5-25 ghz, vertical polarity, tx on channel 3

AC LINE CONDUCTED EMISSIONS, CHANNEL3 RX, L1

AC LINE CONDUCTED EMISSIONS, CHANNEL3 RX, L2

Channel 1 TX, 6dB occupied bandwidth

Channel 3 TX, 6dB occupied bandwidth

Channel 6 TX, 6dB occupied bandwidth

FCC ID : OOX-NCL1100

3 KiloHertz Spectral Density; channel 1

3 KiloHertz Spectral Density; channel 3

3 KiloHertz Spectral Density; channel 6

Conducted RF emissions from the antenna port, channel 1

FCC ID : OOX-NCL1100

Conducted RF emissions from the antenna port; channel 3

Conducted RF emissions from the antenna port, channel 6

Subject: Processing Gain Measurements -Reply

This is in response to your e-mail dated December 4, 1998. With respect to your proposed "Reference Design," after discussing the issue here, we have decided that Harris should obtain an authorization (FCC ID) for the reference design (even if you never actually market this product). In this way, your customers may submit a copy of the processing gain (jamming margin) data from the granted application with their own applications, assuming they are using the exact same design. They would simply have to submit a statement verifying that the design is identical, along with the copied data. The advantage of this approach is that they will be referencing an authorized product, and not some unapproved design, thus avoiding any appearance of impropriety.

I hope this has been responsive to your inquiry. Please contact me with any additional questions.

FCC 15.247(e) Jamming Margin Test
