

Section 2.1.2 states that there are two modes of operation. It then goes on to describe one mode as periodic, and the second mode as an emergency condition mode. The EUT is incapable of changing its peak output power level, and such remains constant in both modes described. If it did change power levels between modes, we would be required to test and demonstrate compliance under such conditions. We have clarified this text in an updated report exhibit now uploaded.

Note: Specific timing details of emergency condition modes have never been required to be tested separately in prior applications, as the regulations put few limits on their activities during an emergency condition.
